EXPERIMENT 07

Zoho Service Integration

Project: Insurance Claim Management using Low-Code in Zoho Creator

AIM

To integrate an Insurance Claim Management application with a configured service for claim notifications or data exchange.

REQUIREMENTS

• Zoho Creator application with Claims, Policyholders, and Policies forms

• Authorized service connection if an external service is used

• Sample claim record

DESIGN / MODULES

Component	Purpose
Policyholders	Policyholder ID, name, contact details
Policies	Policy number, policy type, coverage limit, validity dates
Claims	Claim ID, policyholder, policy, claim date, amount, documents, status
Integration log (optional)	Event, response status, timestamp

PROCEDURE

1. Open the Insurance Claim Management app and confirm the required forms and field link names.

2. Select a suitable service, such as an email notification action or an approved external API.

3. Configure and authorize the connection using the supported authentication method. Keep secrets out of visible fields and shared code.

4. Create a workflow triggered by claim submission or a claim-status update.

5. Map the claim ID, policy number, amount, status, and recipient to the notification or service request.

6. Test with sample data and record the actual response. Do not mark the integration successful until verified.

SAMPLE LOGIC / OUTPUT

Illustrative workflow: when a claim status changes to “Approved”, trigger a configured notification containing the claim reference and status. Configure the actual action and recipient in Zoho Creator.

TEST CASES

Test	Expected outcome
Claim submitted	Submission workflow runs
Claim approved	Approval notification is triggered
Service unavailable	Failure is recorded or handled safely

RESULT

The integration design and test cases are documented. Completion depends on configuring the connection and verifying a real successful response.
